

Public whole-genome demonstration

HG002 · Genome in a Bottle

Sanitized public demonstration generated from an end-to-end GenomeLens analysis of publicly released Genome in a Bottle data.

This public report contains a selected allowlist of results from the analysis. It is not the production GenomeLens report and does not expose the private analysis engine.

DATASET PROVENANCE

SOURCE Genome in a Bottle	REFERENCE BUILD GRCh38	BENCHMARK RELEASE v4.2.1	BENCHMARK SCOPE chr1-22
-------------------------------------	----------------------------------	------------------------------------	-----------------------------------

EXTERNAL BENCHMARK

CONCORDANT 169/169	EXPLICIT TRUTH CALLS 169	MISMATCHES 0	NORMALIZATION FAILURES 0
------------------------------	------------------------------------	------------------------	------------------------------------

Concordance is measured on positions where the truth set states a genotype, inside the defined confident regions. It is not whole-genome accuracy, not clinical validation, and not an endorsement by NIST or GIAB.

SELECTED GENOMIC RESULTS

FINDING	CATEGORY	DISPOSITION	EVIDENCE BASIS
Celiac Disease Susceptibility (second-most-common allele) carrier -- susceptibility_allele	carrier	unresolved	curated clinical evidence
CYP2D6 Intermediate Metabolizer (IM) (codeine / antidepressants)	pharmacogenomics	conditional	published pharmacogenomic guideline evidence
Elevated type-2-diabetes polygenic risk	polygenic risk	conditional	published association evidence

A representative selection, one per category. The full sanitized analysis contains more results than are shown here.

HEALTH-ECONOMIC RESULTS

REFERENCE-CASE NMB \$158.72	CANONICAL EXPECTED NMB \$700.00	INCREMENTAL COST \$871.10	INCREMENTAL QALYS 0.0103
ICER 84,588	PROBABILITY COST-EFFECTIVE 51.9%	NOTE Reference-case and canonical pathway results answer different questions and are never summed.	

Evidence basis. Genomic findings rest on curated clinical evidence; published association evidence; published pharmacogenomic guideline evidence. The economic figures are modeled estimates built on published evidence and stated assumptions, not realized savings.

For nontechnical readers. These results are a research demonstration of what GenomeLens can produce from real whole-genome data. The benchmark measures agreement only at the specific GIAB locations tested and is not a claim of whole-genome or clinical accuracy. The health-economic figures are modeled estimates based on published evidence and assumptions; they are not a diagnosis, medical advice, or a statement that a genome is literally “worth” a particular dollar amount.

SCOPE AND LIMITATIONS

- Public demonstration output; not clinical validation.
- Benchmark scope is limited to the stated GIAB panel and chr1-22.
- Modeled economics are not realized savings.
- Representative findings only; the full sanitized report is the complete output.
